

!! This is the **BUILD IN RENDER PIPELINE** version of this asset, while it should work it has limited support !!

Introduction

Package for blending seams in between meshes as a post process in BiRP.

This effect tries to make different objects transition more nicely

feel free to modify/use this asset as you see fit but please credit.

Usage

There is a reference scene in the assets but this is how to set it up in a new scene:

To use this in your project you need to add the SeamBlendScript component to your camera GameObject.

Then select the PostSeamBlend material (or a inherited version) and the ObjectIDShader.

Blend settings can be changed from the PostSeamBlendMaterial.

Note: Blend radius and depth falloff are somewhat related to your camera settings so will probably need to be adjusted per project.

If your camera settings update at runtime i.e. FOV changes or similar. You will need to call UpdateCamera() in the SeamBlendingScript.

Settings:

Blend iterations: **most expensive setting**, mainly affects the amount of visible bands at the seams, setting this really high can cause a crash, recommended value: ~5-20

Depth Margin: changes a margin used for checking depth, setting too low can cause visual glitches i.e. shadow acne. Too high values cause ignored layers to be less effective at masking.

Blend Radius: Radius of transition.

Depth Falloff: causes effect to diminish at larger distances between objects at seam.

You can disable/enable the effect for certain objects in the "ID Layer mask" inside the script component.

Known problems:

Some known problems with the built in RP version of the asset.

- Transparent objects don't blend correctly and will not mask the effect of objects behind them.
- Effect does not work in scene view
